

Abstract

A covering arrangement (10) for a building has parallel
elongate supports (14) and covering parts (16) arranged
5 thereon. The covering parts comprise a core (22) and,
connected thereto, upper covering elements (24) and lower
planar covering elements (26), with the result that a
sandwich is formed. The covering parts (16) furthermore
have an elongate, striplike form and in the installed
10 position are arranged transversely to the supports (14),
extending at least from one support (14) to a neighbouring
support (14). In order to increase the resistance to wind
loads, it is proposed that a longitudinal border
region (30) of a covering part (16) comprises a connecting
15 device (68) and the opposite longitudinal border
region (34) of a neighbouring covering part (16) has a
connecting device (70) complementary thereto, by means of
which the two covering parts (16) are firmly connected to
each other.
